

Website Title: Texas Rain Storms Set to Bring Toxic Worms, Pet Parents Beware

Email Headline: Slimy INVASION - Texas Flooded With THIS

The state of Texas is reportedly preparing for a dangerous [invasion](#). Not an invasion by a domestic threat, or that of another country, but instead an insect invasion that is reported to be harmful to pets and animals. Texans have been experiencing heavy rain and windy conditions since late April and are now preparing for more heavy rain and flash flooding.

The Lone Star state is bracing for an [upcoming rainstorm](#), which is alleged to unleash large numbers of toxic mutant worms, which are reported to grow over a foot in length, as well as regenerate if cut in half. Experts have revealed that the toxic worms are called hammerhead flatworms, due to the shape of their heads and bodies. The flatworms are capable of spreading a toxic poison that can be harmful to humans but even more dangerous to animals.

Scientists have warned the public to stay away from the invasive worms, which are known to feast on snails, earthworms, and other ground insects. The hammerhead flatworm uses its toxins to paralyze its prey, a toxin similar to that found in lethal puffer fish. The heavy rain heading towards Texas is expected to flush the flatworms out of their burrows underground.

What makes the flatworm more dangerous is the fact that it can regenerate, making it almost immortal. Expert Ashley Morgan-Olvera of the [Texas Invasive Species Institute](#) stated to Houston news outlet KHOU 11 that when cut in half, two worms will form. Entomology expert Dr. Blake Layton Jr. explained that once the worm is cut in half, the rear portion grows a new head, creating a worm almost identical to its parent.

Experts have warned people not to touch the worms, even if they are dead. If contact is made, the public has been advised to wash their hands with soap and disinfectant immediately after. It is believed that the worms may also carry harmful parasites.
